# Vulture and Vermin Restaurant

An aerial photograph showing a large, open pyre of burning carcasses in a green field. A massive plume of white smoke rises from the pyre, drifting towards the left. To the right of the pyre is a farm with several buildings, including a large blue-roofed structure. The surrounding area is a mix of green fields and some bare trees.

## The Least Desirable Method

**OAB: FMD carcasses on an open pyre at a farm in UK**

# Not a Compost Pile!

# Compost Pile

# Windrows

(Courtesy: John Kube of Elanco Animal Health, Greenfield, IN).

# Pile Structure and Composition

- Pile is composed of a three-phase system
  - Solid, Water, Air
- Solids- Varying particle sizes, geometry and chemical composition
- Voids-Filled with air, water or both
- C:N ♥ Porosity ↓ Liquid ↑

# Pile Composition...

## ■ Composting Feedstock (C:N ~35)

- Plant and animal based with microorganisms

## ■ Bulking Agent

- Generally plant based for structural strength, bulking and drying wetter piles

## ■ Biofilter

- Dry, Carbon-rich plant-based materials for odor reduction, shedding moisture and predator control

## ■ Shape and Dimensions

Height: Five to seven feet

Top: Pointed, Flat or Slightly concave

Sides: Slopping to shed water

# Carcass Compost Pile Cross-section

# Effect of Pile Physical Properties

## ■ Water (50%-60%)

- For nutrient transport to microbes
- Excessive moisture in pores reduces oxygen diffusion and transfer
- Impedes aerobic composting activity
- Fibrous/bulky materials such as wood shavings and straw absorb more moisture but maintain structure
- Sludge and grass clippings may compact/settle under larger carcasses and reduce pile porosity

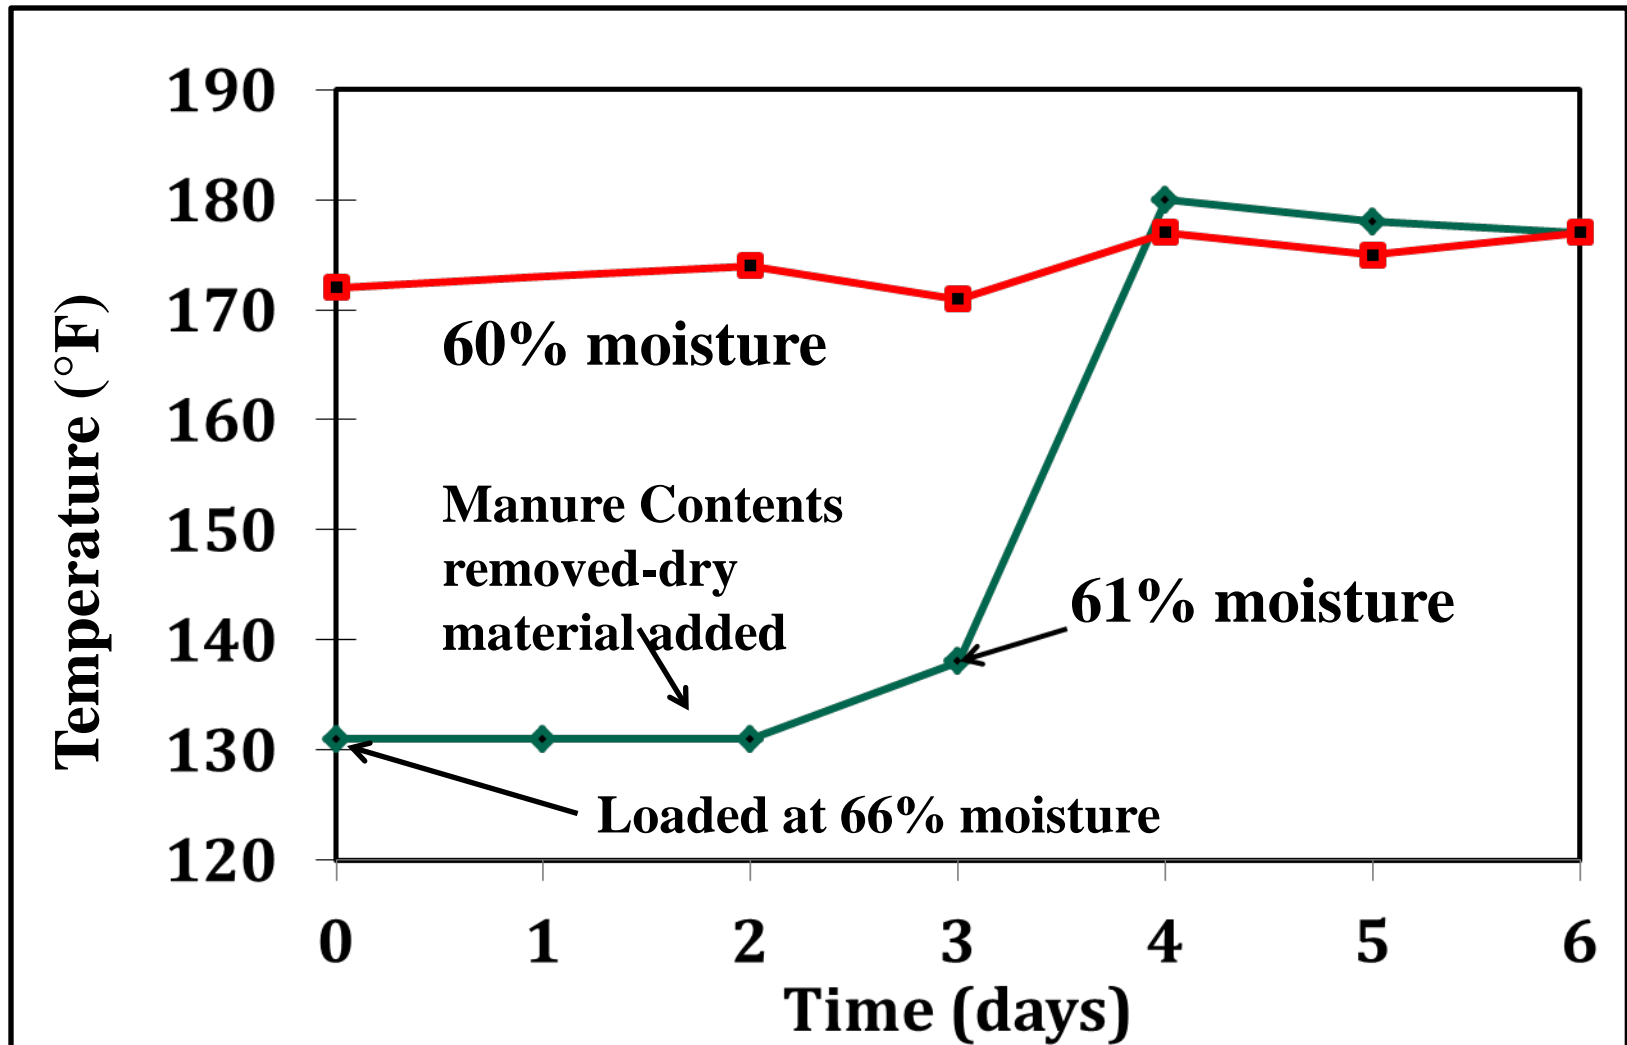

## **Maximum Recommended Moisture Content\***

<b>Type of Waste</b>	<b>Moisture Content (% of total weight)</b>
<b>Theoretical</b>	<b>100</b>
<b>Straw</b>	<b>75–85</b>
<b>Wood (sawdust, small chips)</b>	<b>75–90</b>
<b>Rice hulls</b>	<b>75–85</b>
<b>Municipal refuse</b>	<b>55–65</b>
<b>Manures</b>	<b>55–65</b>
<b>Digested or raw sludge</b>	<b>55–60</b>
<b>“Wet” wastes (grass clippings, garbage, etc.)</b>	<b>50–55</b>

## Effect of Initial MC on Temperature During Composting\*

\*Graph reproduced from Haug, R.T. CRC Press, 1993

# Effect of Pile Physical Properties

## ■ Porosity and Free Airspace

- Porosity  $\rightarrow V_v/T_v$
- Free airspace  $\rightarrow$  Gas volume/Total volume
- Total porosity Vs. Free airspace

# Case Studies – Pile Characteristics

# Cow Mortality (1,300 Lbs) Compost

## Feedstock: Fresh and Composted Manure Solids

C:N 20, MC 50%

# Pile and Ambient Temperatures

# Cow Mortality (2,000 lbs) Composting

Feedstock C:N= 49, MC = 41.4%

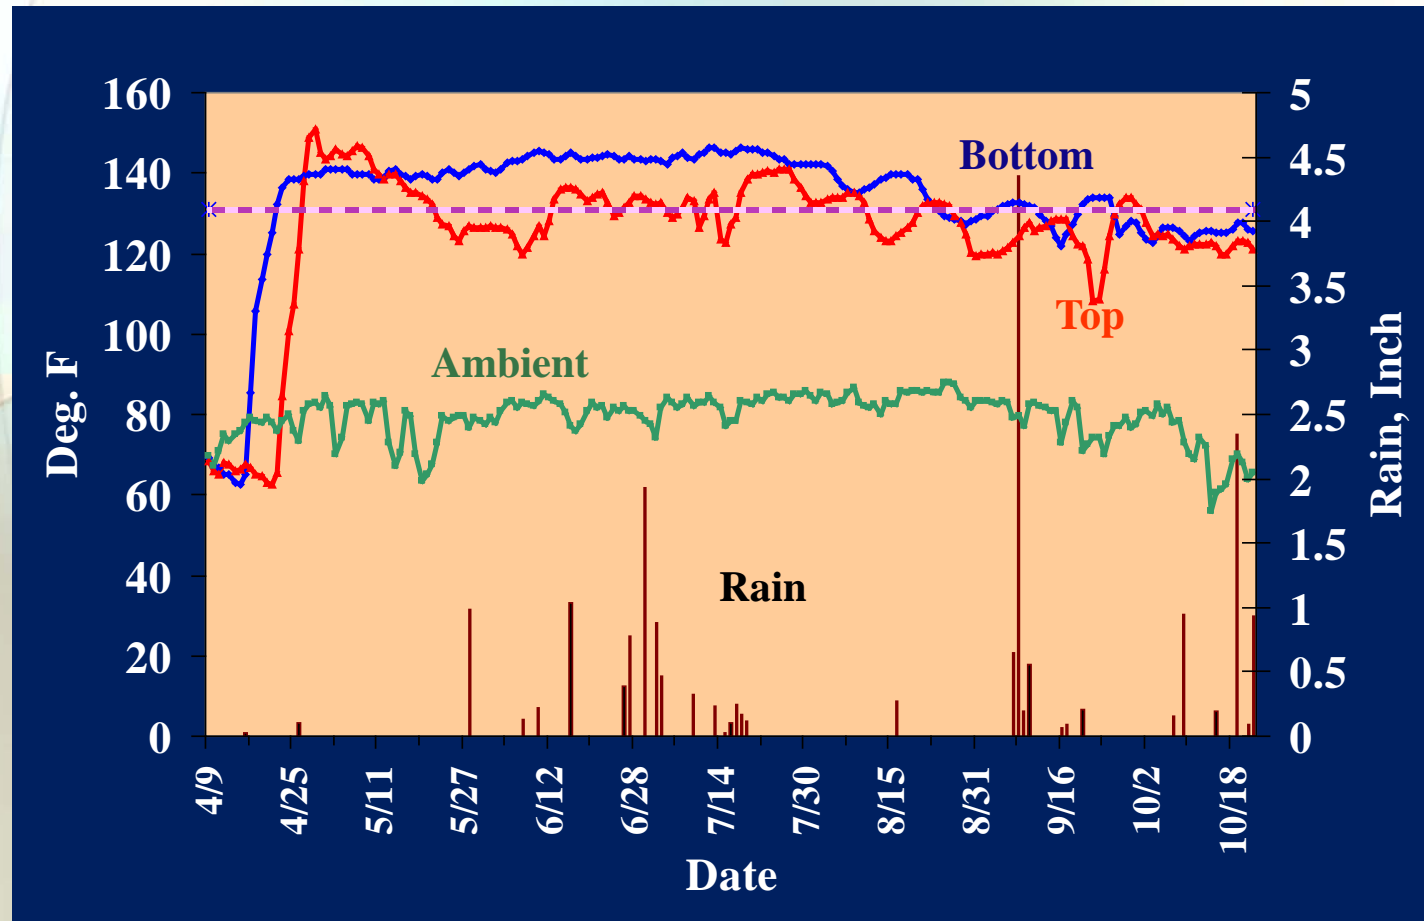

# HORSE BEDDING SUBSTRATE

# Pile and Ambient Temperatures

# Pile and Ambient Temperatures

# Summary

**Pile feedstock, moisture, porosity and free airspace impact the outcome of a composting carcass**

- Start pile with a C:N > 25....35 is better
- Initial pile moisture at 50-60%, No less than 40%
- Use bulking and biofilter materials, if and needed
- Select proper feedstocks to maintain 30 to 40% airspace

**Carcass composting requires a ‘common sense’ approach**

# Happy Composting!
